Full Marks : 70

Pass Marks : 21

Time : Three hours

Q.N o.	Option/Ans/Key point	weightage	Marks
SECTION: A			
1.	B infinitely charged thin plane sheet	1	1
2.	C $r = mv/Bq$	1	1
3.	D upwards	1	1
4.	A inductor	1	1
5.	D $P/\sqrt{2}$	1	1
6.	D $\hat{j} \times \hat{k} = \hat{i}$	1	1
7.	C -5cm $P_2 = P - P_1 = -10 - 10 = -20$, $f_2 = 100/P_2$ cm = -5cm	1	1
8.	C $R/2$	1	1
9.	D $E = MC^2 \Rightarrow M = E/C^2$	1	1
10.	D $v_3 = v/3$, as $v \propto 1/n$ and for second excited state $n=3$	1	1
11.	C nuclear forces are charge independent	1	1
12.	D	1	1
13.	A	1	1
14.	D	1	1
15.	A	1	1
16.	C	1	1

17.

Potential at P due to any small elemental length dl on the loop is $dV = Kdq/r$

here $r = (R^2 + 4R^2)^{1/2}$

$$V = \int dV = \int Kdq/r = \int K\lambda dl/r$$

$$= K\lambda 2\pi R / (R^2 + 4R^2)^{1/2} = \frac{\lambda}{2\sqrt{5} \epsilon_0}$$

 $\frac{1}{2}$

2

 $\frac{1}{2}$ $\frac{1}{2} + \frac{1}{2}$

18. $c = E_0/B_0 \Rightarrow B_0 = E_0/c = 120/3 \times 10^8 = 4 \times 10^{-7} \text{T}$

$$\omega = 2\pi\nu = 2 \times 3.14 \times 50 \times 10^6 = 3.14 \times 10^8 \text{ rad s}^{-1}$$

$$k = \omega/c = 3.14 \times 10^8 / 3 \times 10^8 = 1.05 \text{ rad m}^{-1}$$

$$\lambda = c/\nu = 6.00 \text{ m}$$

OR

An oscillating charge produces an oscillating electric field in space, which produces an oscillating magnetic field, which in turn, is a source of oscillating electric field and so on. The oscillating electric and magnetic fields thus regenerate each other, as the wave propagates through space.

The frequency of the electromagnetic wave equals the frequency of oscillation of the charge.

<p>26.</p>	<p>(a) work done in aligning a magnet from orientation θ_1 to θ_2 is given by</p> $W = -mb (\cos\theta_2 - \cos\theta_1)$ <p>i. $\theta_1=0^\circ, \theta_2=90^\circ$</p> $W = -mB(0-1) = mB = 1.5 \times 0.22 = 0.33 \text{ J}$ <p>ii. $\theta_1=0^\circ, \theta_2=180^\circ$</p> $W = -mB(-1-1) = 2mB = 2 \times 1.5 \times 0.22 = 0.66 \text{ J}$ <p>(b) Torque = $mb \sin\theta$</p> <p>i. torque = $mb \sin 90^\circ = 1.5 \times 0.22 \times 1 = 0.33 \text{ J}$</p> <p>ii. torque = $mb \sin 180^\circ = 0$</p> <p style="text-align: center;">OR</p> <p>We know that F is an attractive (-) force when the currents are like currents. i.e. the product of currents is positive.</p>	<p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>$\frac{1}{2}$</p> <p>3</p>

similarly F is a repulsive(+) force when the currents are unlike. i.e. the product of currents is negative.

$3 \times 1 = 3$

27.

According to Kirchoff's junction rule at E or B $I_3 = I_1 + I_2$

Since $I_2 = 0$, $I_3 = I_1$

using loop rule in AFEBA $2I_3 + 3I_3 + I_2 R_1 = 10$

$\Rightarrow 5I_3 = 10 \Rightarrow I_3 = I_1 = 2A$

The potential difference between A and D, along the branch AFED of the closed circuit,

$V_A - 2I_3 + 1 - 3I_3 - V_D = 0$

$V_A - V_D = 2I_3 - 1 + 3I_3 = 2 \times 2 - 1 + 3 \times 2 = 9V$

31.

Flux through the Gaussian surface = flux through the curved cylindrical part of the surface = $E \times 2\pi r l$

The surface includes a charge equal to $= \lambda l$.

Gauss's law then gives $E \times 2\pi r l = \lambda l / \epsilon_0$

i.e., $E = \lambda / 2\pi\epsilon_0 r$ Vectorially,

E at any point is given by $E = \lambda / 2\pi\epsilon_0 r \hat{n}$

work done in moving the charge q through small distance dr is $dW = \mathbf{F} \cdot d\mathbf{r} =$

$$qE dr = \frac{q\lambda dr}{2\pi\epsilon_0 r} \text{ on integrating between } r_1 \text{ to } r_2 \quad W = \frac{\lambda q}{2\pi\epsilon_0} \ln \frac{r_2}{r_1}$$

OR

$$\text{Correct derivation of } C = \frac{\epsilon_0 A}{d - t + \frac{t}{k}}$$

expression in case of fully filled dielectric $C = \epsilon_0 A / d$

given $C_x = c$ and $C_y = 4c$

as both are in series $C_{\text{eff}} = c * 4c / (c + 4c) = 4C / 5 = 4$

a.

- b. Principle: mutual Induction, i.e. change in current passed through one coil will induce the emf in the inductively coupled second coil.

$$\text{derivation of } V_s/V_p = N_s/N_p$$

$$c. E_s/E_p = N_s/N_p \Rightarrow E_s = (40000/200) \times 220 = 44,000V$$

potential difference per turn is $E_s/N_s = 44000/40000 = 1.1 V$

OR

a. a- capacitive $X_c = \frac{1}{\omega C}$

b- Inductive $X_L = \omega L$

- b. i. Phase difference between voltage and current in all the three components are not the same, we cannot add them algebraically. The phasors are to be treated as vectors.

So, the vector sum of voltages which is equal to voltage of the source.

$$V_{eff} = \sqrt{V_R^2 + (V_L - V_C)^2}$$

$$= \sqrt{200^2 + (250 - 250)^2} = 200V$$

ii. As we know $I_{rms} = \frac{V_{rms}}{Z}$

here, as $V_L = V_C$ circuit is in resonance

in resonance $Z=R$

$$I_{rms} = \frac{V_{rms}}{Z} = \frac{V_{rms}}{R} = 200/40 = 5A$$

b. any two differences such as

(i) The interference pattern has a number of equally spaced bright and dark bands. The diffraction pattern has a central bright maximum which is twice as wide as the other maxima. The intensity falls as we go to successive maxima away from the centre, on either side.

(ii) We calculate the interference pattern by superposing two waves originating from the two narrow slits. The diffraction pattern is a superposition of a continuous family of waves originating from each point on a single slit.

(iii) For a single slit of width, a , the first null of the interference pattern occurs at an angle of λ/a . At the same angle of λ/a , we get a maximum (not a null) for two narrow slits separated by a distance a .

c. given $\lambda = 5 \times 10^{-7} \text{m}$, $D = 1 \text{m}$, $y = 2.5 \times 10^{-3} \text{m}$

we know that the half of the width of the central maximum, $y =$

$$\frac{\lambda D}{a} \Rightarrow a = \frac{\lambda D}{y}$$

$$a = 2 \times 10^{-4} \text{m}$$

$$2 \times 1 = 2$$
